Socket Programming - Practice Question

A college is developing a campus communication system in which a client computer sends a greeting message to a central server. The server must listen for incoming connections, accept a client connection, receive the message, and display it on the server terminal. The client should send the message "Hello Server!" using TCP socket programming. Write two Python programs, server.py and client.py, to implement this communication using the socket module. Use IPv4 addressing and port number 12345. Demonstrate the execution of both programs and show the output displayed on the client and server terminals.
